Test Apple Health sync with your iPhone

Stride setup and end-to-end testing guide
Branch: feature/data-setup-onboarding

Use the real iPhone flow. Account > Sync test data returns synthetic server data. It does not test HealthKit. Install the Stride Health companion through Xcode first.

1. Start Stride on your Mac

From the **fitness-mvp** folder, run:

```
git switch feature/data-setup-onboarding
git pull --ff-only
jac install
jac run
```

Open http://localhost:8000. Keep the server running. If port 8000 is occupied, use `jac run --port 8100` and use port 8100 throughout this guide.

2. Install the iPhone companion

You need a Mac with Xcode and an iPhone running iOS 16 or later. Use an Xcode version compatible with your installed iOS version.

• Open `ios/StrideHealth/StrideHealth.xcodeproj` in Xcode. Let it download the SDK dependency.

• Select **StrideHealth > Signing & Capabilities > Team**. Choose your development team; use a unique bundle identifier if Xcode requests one.

• Connect your iPhone, select it as the run destination, and press **Run**. Enable Developer Mode or trust the developer profile if prompted.

3. Confirm the phone can reach your Mac

Connect both devices to the same Wi-Fi. In iPhone Safari, open the Mac's network address printed by `jac run`, for example `http://192.168.1.20:8000`. Replace that example with your Mac's actual address. Do not use `localhost` on the phone.

Checkpoint: Stride must load in iPhone Safari before syncing can work. Campus or guest Wi-Fi may block device-to-device traffic; try home Wi-Fi or a hotspot.

Run the sync and verify it

Keep the Mac server, browser page and Stride Health companion open.

4. Request the real Apple Health sync

In the Stride web app, choose:

Data settings > Fill it from connected apps > storage choice > Apple Health > Continue > Finish setup

Under **Weekly averages**, click **Send sync request to iPhone**. Scan the QR code with your iPhone camera. If the web page is already open on the iPhone, tap **Open in Stride Health**. The companion must already be installed.

5. Authorize and check the result

• In Stride Health, check that the server address is your Mac. Tap **Allow and sync**.

• Allow the requested Health permissions and local-network access. Keep the companion open until it reports completion.

• Return to Stride in the browser. Available averages should fill automatically: **daily steps, heart rate, sleep hours and workouts per week**, using the last 28 days.

• Review the values before creating a week. **The calorie target should remain unchanged.** An account is not required to test the QR-based sync.

If the test does not work

• **No connection:** first repeat the Safari network check. Confirm the server is still running and use the correct port. Allow local-network access if prompted.

• **QR code does not open the companion:** make sure Stride Health is installed, then generate a new request. Requests expire after 15 minutes without activity.

• **Some averages are blank:** the Health app may have no recent data for that metric, or read access may have been declined. HealthKit does not tell Stride which read permissions were denied.

• **Controlled sample:** use a simulator or manually add sample data in Health, then send a new request. Use yesterday for test steps: Stride excludes today's steps from its daily average. Do not expect an exact match to every Health app total; Stride uses its own source de-duplication.

Testing status: Web QR creation and server tests pass. The companion has not yet been verified with a physical iPhone; this first end-to-end test may expose an Xcode build or device issue.

Reference instructions

Apple: Run your app on a physical device
Apple: Manage and manually add Health data
